Excerpt: . . . relative efficiencies of catalysts for ammonia synthesis. Actually, such a catalyst is not employed in technical synthesis owing to its great sensitivity to catalyst poisons. Catalytic agents composed of iron admixed with suitable promoters are preferred to the uranium carbide, although catalytically less efficient, owing to their greater resistivity to traces of foreign gases such as carbon monoxide or sulphur compounds. 1 (Similar observations on the equilibrium factors in other catalytic reactions may be obtained in Rmnsr. and TAYLOR, loc cit. pp. 83, 91, 101, 162, 237, 302.) The measurement of the reaction velocity is relatively simple in the case of homogeneous catalytic reactions, since the concentrations of the several constituents and the course of the reaction can generally be readily ascertained. With heterogeneous reactions the problem is more complex since the several magnitudes required are not capable of precise statement. In illustration...
